DATE Aug 14 1955
CASE No. 1

As shown in preceding hand file
in notes, the tunneling and breakdown
will be possible. Tunneling will be
possible because of equal energy electrons
of the same energy and under
the condition stated above, however no
allowed states of same energy in the
adjacent conduction bands. Unstable
lowest energy because an electron on left
falling over the potential step must give
up energy equal to that necessary to
create a hole-electron pair. Consequently,
the current will drop as the applied bias
is increased. Finally, at higher
biases, the normal diode forward
characteristic will be observed.

50年後

Esaki diode is still a radio star, half a century on

An FM transistor radio owned by one of us (L. E.) since the early 1960s still works beautifully. Reasoning that this was testament to the performance of its single Esaki diode, we tested the effects of storage on some of these germanium devices made in 1960.

The Esaki diode (L. Esaki *Phys. Rev.* **109**, 603-604; 1958) was the first quantum-electron

device. Unlike the mechanism that powers most semiconductor devices, current flows through the diode as a result of quantum-mechanical electron tunnelling across a potential barrier.

Semiconductor transport devices are extremely stable, so their shelf-life should be infinite if they are stored at room temperature. But the Esaki diode's tunnel current is very sensitive to its enormous built-in electric field in the junction region (E. Spenke *Electronic Semiconductors* 232; McGraw-Hill, 1958), which could affect its long-term performance.

As the most likely indicator of any small structural changes in the device, we re-measured the peak current in 20 devices and discovered that it had fallen by an average of just 3.3% over 50 years, corresponding to a junction widening of only 0.25%.

This very tiny shift in electronic characteristics is probably down to inbuilt impurities and imperfections within the structure. A gratifying confirmation of the diode's longevity, nonetheless.

- **周期ポテンシャルとバンドギャップ**
- 有効質量近似

分子軌道の観点から

s/p 軌道が結合/反結合状態を形成して分裂

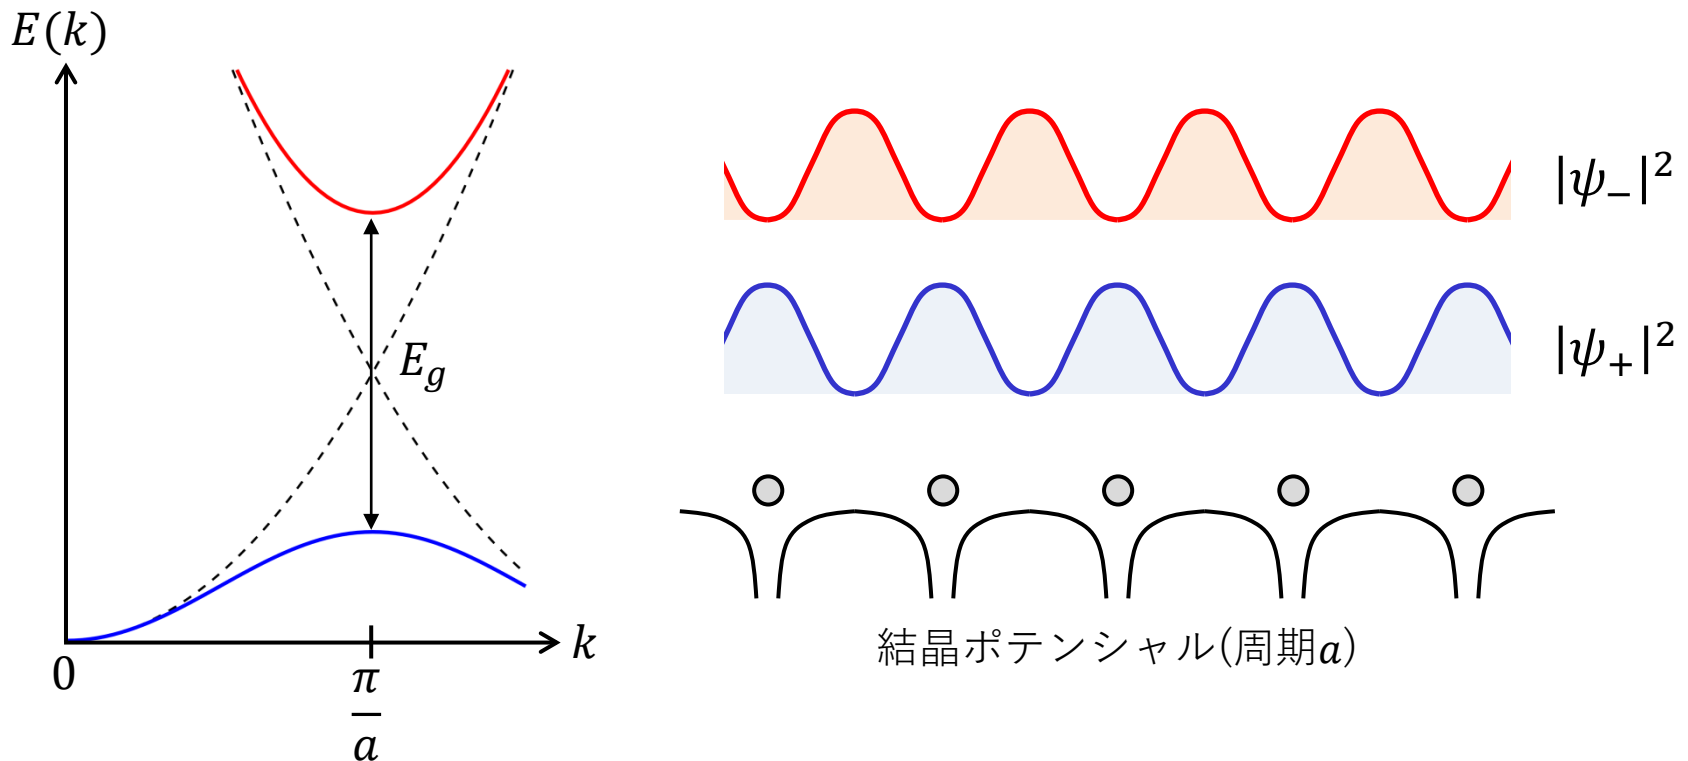

自由電子近似の観点から

右向きと左向きの進行波が $k = \pi/a$ でブラッグ反射して定在波を形成

同位相 $\psi_+(x) = e^{i\pi x/a} + e^{-i\pi x/a} = 2 \cos(\pi x/a)$

逆位相 $\psi_-(x) = e^{i\pi x/a} - e^{-i\pi x/a} = 2i \sin(\pi x/a)$

1D周期ポテンシャル中の電子

ポテンシャル形状を仮定せずに一般論を進める

単独の障壁ポテンシャル(偶関数)

$$v(x) = v(-x) \quad -\frac{a}{2} \leq x \leq \frac{a}{2}$$

$$V(x) = \sum_{n=-\infty}^{\infty} v(x + na)$$

$$V(x + na) = V(x)$$

シュレディンガー方程式

周期的境界条件付の自由電子

$$H_0\varphi(x) = -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} \varphi(x) = \epsilon\varphi(x) \quad \varphi(x + Na) = \varphi(x)$$

$$\Rightarrow \varphi_k(x) = e^{ikx} \quad \epsilon = \frac{\hbar^2 k^2}{2m} \quad k = \frac{2\pi}{Na} p \quad (p = 0, \pm 1, \pm 2, \dots)$$

さらに格子周期のポテンシャルが加わる

$$H\psi(x) = [H_0 + V(x)]\psi(x) = \epsilon\psi(x)$$

ブロッホの定理

並進演算子 $Tf(x) = f(x + a)$ $[T, H] = TH - HT = 0$

$$TH(x)\psi(x) = H(x + a)\psi(x + a) = H(x)T\psi(x)$$

$\psi(x)$ は H と T の同時固有関数なので $T\psi(x) = \lambda\psi(x)$

$$\psi(x + a) = e^{ika}\psi(x)$$

$$\psi(x) = e^{ikx}u_k(x)$$

$$u_k(x + a) = u_k(x)$$

$$T^N\psi(x) = \lambda^N\psi(x) = \psi(x)$$

$$\lambda = e^{i\left(\frac{2\pi p}{Na}\right)a} = e^{ika}$$

$$e^{ik(x+a)}u_k(x + a) = e^{ika}(e^{ikx}u_k(x))$$

ポテンシャル領域(独立な解の重ね合わせ)

$$\psi(x) = A\psi_L + B\psi_R \quad -\frac{a}{2} \leq x \leq \frac{a}{2}$$

+ブロッホの定理

ブロッホの定理を適用

$$\psi(x + a) = e^{ika} \psi(x)$$

$$x = \frac{a}{2} \quad \psi(x) = Ate^{iKx} + B(e^{-iKx} + re^{iKx})$$

$$\psi\left(-\frac{a}{2} + a\right) = Ate^{iKa/2} + B(e^{-iKa/2} + re^{iKa/2})$$

$$x = -\frac{a}{2} \quad \psi(x) = A(e^{iKx} + re^{-iKx}) + Bte^{-iKx}$$

$$e^{ika} \psi\left(-\frac{a}{2}\right) = e^{ika} [A(e^{-iKa/2} + re^{iKa/2}) + Bte^{iKa/2}]$$

$$A(te^{iKa/2} - e^{ika} e^{-iKa/2} - re^{ika} e^{iKa/2})$$

$$= B(te^{ika} e^{iKa/2} - e^{-iKa/2} - re^{iKa/2})$$

ブロッホの定理を適用

$$\psi'(x+a) = e^{ika} \psi'(x)$$

$$x = \frac{a}{2} \quad \psi'(x) = iKAte^{iKx} - iKB(e^{-iKx} - re^{iKx})$$

$$\psi'\left(-\frac{a}{2} + a\right) = iKAte^{iKa/2} - iKB(e^{-iKa/2} - re^{iKa/2})$$

$$x = -\frac{a}{2} \quad \psi'(x) = iKA(e^{iKx} - re^{-iKx}) - iKBte^{-iKx}$$

$$e^{ika} \psi'\left(-\frac{a}{2}\right) = iKe^{ika} A(e^{-iKa/2} - re^{iKa/2}) - iKe^{ika} Bte^{iKa/2}$$

$$\begin{aligned} & A(te^{iKa/2} - e^{ika}e^{-iKa/2} + re^{ika}e^{iKa/2}) \\ & = B(-te^{ika}e^{iKa/2} + e^{-iKa/2} - re^{iKa/2}) \end{aligned}$$

振幅 A, B を消去

$$\frac{B}{A} = \frac{te^{iKa/2} - e^{ika}e^{-iKa/2} - re^{ika}e^{iKa/2}}{te^{ika}e^{iKa/2} - e^{-iKa/2} - re^{iKa/2}}$$

$$= \frac{te^{iKa/2} - e^{ika}e^{-iKa/2} + re^{ika}e^{iKa/2}}{-te^{ika}e^{iKa/2} + e^{-iKa/2} - re^{iKa/2}}$$

$$\begin{aligned}\cos ka &= \frac{t^2 - r^2}{2t} e^{iKa} + \frac{1}{2t} e^{-iKa} \\ &= \frac{e^{2i\delta}}{2|t|e^{i\delta}} e^{iKa} + \frac{1}{2|t|e^{i\delta}} e^{-iKa} \\ &= \frac{\cos(Ka + \delta)}{|t|}\end{aligned}$$

$$|t|^2 + |r|^2 = 1$$

$$t = |t|e^{i\delta}$$

$$r = i|r|e^{i\delta}$$

エネルギーギャップ

$$\cos ka = \frac{\cos(Ka + \delta)}{|t(K)|} = f(K) \quad E = \frac{\hbar^2 K^2}{2m}$$

一般に、 $|t| < 1$, δ は K に依存($K \rightarrow \infty, t \rightarrow 1$)

$|f(K)| < 1$ となる領域が許容帯となる(満たす k が存在)

$$\begin{aligned} \chi(\mathbf{l}' + \mathbf{l}) &\approx e^{\mathbf{l} \cdot \nabla} \chi(\mathbf{l}') \\ &\approx e^{i\mathbf{k}' \cdot \mathbf{l}} \chi(\mathbf{l}') \end{aligned}$$

$$-i\nabla \leftrightarrow \mathbf{k}$$

有効質量近似

$$\sqrt{N} \int a^*(\mathbf{r} - \mathbf{l}') H \Psi(\mathbf{r}) d\mathbf{r} = \varepsilon(\mathbf{k}') \chi(\mathbf{l}') \quad (H + U)\Psi = E_u \Psi$$

$$\sqrt{N} \int a^*(\mathbf{r} - \mathbf{l}') U \Psi(\mathbf{r}) d\mathbf{r} = U(\mathbf{l}') \chi(\mathbf{l}') \quad \varepsilon(\mathbf{k}) = E_c + \frac{\hbar^2 \mathbf{k}^2}{2m^*}$$

$$\sqrt{N} \int a^*(\mathbf{r} - \mathbf{l}') E_u \Psi(\mathbf{r}) d\mathbf{r} = E_u \chi(\mathbf{l}')$$

結晶ポテンシャル

有効質量近似

注意点

- 格子周期に対しゆるやかな変化が前提(ドナー近傍、ヘテロ界面?)
- 単一バンドのみ考慮(バンド間遷移は無視)
- 間接遷移半導体には、谷の縮退がある(谷-軌道相互作用、有効質量の異方性)
- アクセプター不純物では、価電子帯頂上の構造(重い正孔・軽い正孔)を考える必要があり、かなり複雑

最近の理論の進展

ドナー不純物を用いた量子情報処理の実験の進展に伴い、より正確な理論構築の必要性が増している(波動関数の空間分布の計算)
